

Core Switch Flow Control

Overview

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up. Flow control on Ethernet can be implemented at the data link layer. The first flow control mechanism, the pause frame, was defined by the IEEE 802.3 standard. Overview Ethernet flow control is a mechanism for temporarily stopping the transmission of data on the Ethernet family of protocols. The goal of this mechanism is to avoid buffer overflow in the presence of congestion. Another effort began in March 2004, and in May 2004, it became the IEEE P802.3ar Congestion Management Task Force. In May 2006, the objectives of the task force were revised to specify a mechanism to limit the transmission rate. • TechFest Ethernet Technical Summary. 1999.
