

# Fiber optic channel congestion

## Overview

Fiber optic congestion is the occurrence of delays or losses in the transmission of data packets due to the density of data traffic on the network. This can negatively affect network. Fibre Channel Storage Area Networks (SANs) have long been experiencing congestion issues that degrade performance and disrupt critical business operations. This article explores the transformative role of artificial intelligence in revolutionizing congestion detection and resolution within FC. In high-performance storage networks, congestion happens from time to time and can become a barrier to business efficiency, reliable application performance, and in extreme cases, application availability. Miniaturized fibre cables have a significantly smaller diameter compared to traditional cables. This reduction in size allows more fibres to be installed in the same duct.
