

Maximum heat resistance temperature of optical cable

Overview

Standard cables often max out around 85°C to 125°C. However, high-temperature specialized fibers, employing polyimide or other advanced coatings, can endure continuous operation at 300°C and even survive short-term exposures near 490°C. Most standard optical fibers operate reliably down to -40°C, but temperatures below this threshold cause significant performance degradation: Silica glass—the core material of optical fiber—has an extremely low thermal expansion coefficient ($\approx 0.5 \times 10^{-6}/^{\circ}\text{C}$), meaning it barely shrinks or expands with. Fiber optic cables are designed with different material thresholds. It is. Thus, the conjugation of high power propagation and tight bending, resulting from the actual FTTH infrastructures, is responsible for fibre lifetime reduction, mainly caused by the local increase of the coating temperature.
