

Passive Optical Network Technology and Applications

Overview

A passive optical network (PON) is a fiber-optic telecommunications network that uses only unpowered devices to carry signals, as opposed to electronic equipment. In practice, PONs are typically used for the last mile between Internet service providers (ISP) and their customers. While there are many subtle differences, a clear distinction between active optical networking and PON topology is PON's use of a. For many years, passive optical networks (PONs) have received a considerable amount of attraction regarding their potential for providing broadband connectivity to almost every citizen, especially in remote areas where fiber optics can attract people to populate regions that have been abandoned. Some basic knowledge of optical networks will help in better understanding the course but is not a prerequisite. Often referred to as the “last mile” solution, PON architecture. In the present high-speed digitized environment, Passive Optical Networks (PON) have become a pivotal solution to meet the demands of Big Data. PON primarily utilizes a point-to-multipoint topology and fiber optical splitters to transmit data from a single point of transmission to multiple user.
