

The function of an adjustable level attenuator

Overview

Adjustable Control: Allows the attenuation level to be changed continuously or in steps during operation. **How:** Uses a moving contact (wiper) on a resistive element (like a film or card) or a moving vane in a waveguide. Adjusted manually via a knob or screw. It does not distort its waveform or affect its frequency. Moreover, it acts as a controlled “buffer” between a source and a load, providing a known and precise amount of. An attenuator is a passive broadband electronic device that reduces the power of a signal without appreciably distorting its waveform. This reduction is typically achieved by converting part of the RF signal into heat through resistive materials. **Variable RF Attenuator:** When dealing with radio-frequency signals, it often comes in handy to have an easy way to attenuate a signal level in discrete steps.

Attenuators are usually passive devices made from simple voltage divider networks. Switching between different resistances forms adjustable stepped attenuators and continuously adjustable ones using potentiometers. For higher frequencies precisely matched low voltage standing wave ratio (VSWR) resistance networks are used. Fixed attenuators in circuits are used to lower voltage, dissipate power, and to improve impedance matching
