

The lower the value of the beam splitter the better

Overview

A beam splitter divides incident light into reflected and transmitted beams at a specified R/T ratio. For a lossless beam splitter, $R + T = 1$. These exiting beams are differentiated by either their optical power (non-polarizing) or polarization states (polarizing). It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. Circular beamsplitters, plate beamsplitters and cube beamsplitters can be purchased for polarizing or non polarizing beamsplitting. The beam splitter splits and then recombines infrared radiation, while the detector picks up the resulting signal. It's sensitive to both intensity and frequency. Together, they decide just how accurately an instrument captures those unique infrared “fingerprints” from different substances.
